

The Leverage Cycle

John Geanakoplos

Collateral Levels = Margins = Leverage

- From Irving Fisher in 1890s and before it has been commonly supposed that the **interest rate** is the most important variable in the economy.
- But **collateral** levels are more important in times of crisis.
- Perhaps the **Fed** should pay more attention to collateral levels and pay less attention to interest rates. Is it trying now?

Standard Economic Theory:

Equilibrium (supply = demand) determines interest rate.

In my theory:

Equilibrium determines Margins as well. Surprising that one equation can determine two variables.

Key concept: Leverage Cycle

- Too much equilibrium leverage in normal times
- Bad news
 - lowers expected values
 - increases expected volatility
- Too little leverage in crisis

Historical Examples

- 1930s farms
- 1994 derivatives
- 1998 emerging markets and mortgages
- 2000 subprime (small crash)
- 2007 subprime mortgage crash, housing to follow?

Sub-prime Homeowner

- The problem today is not too high sub-prime interest rates, but too big down-payment.

Natural Buyers and Endogenous Margins Theory of Crashes

The thesis is that a liquidity crisis begins when bad news about assets lowers their prices, which then redistributes wealth away from their natural buyers.

But the crisis only reaches its climax when the margin requirements are tightened.

- i) Asset goes down (slightly) in value when probability of bad outcome objectively rises (slightly).
- ii) This causes big drop in income of **natural buyers** who were leveraged.
- iii) This leads to further loss in its value.
- iv) Then **margin** requirements tightened if volatility increases, for example because time horizon of potential default shortens.
- v) This causes huge loss in its value via forced sales.
- vi) There may be spillovers if sales of other assets forced.
- vii) Investors who remain have great opportunity

I will illustrate this with an example.

“Promises Promises”

Endogenous Collateral with Heterogeneous Beliefs: A Simple Example

Let each agent $h \in [0,1]$ assign probability h to **U** and probability $1 - h$ to **D**. Agents with h near 1 are optimists, agents with h near 0 are pessimists.

Suppose that **X** is perfectly durable if warehoused and extinguished if consumed (like tobacco). Suppose that 1 unit of **Y** gives 1 unit of **X** in state **U** and $R=.2 < 1$ units of **X** in **D**.

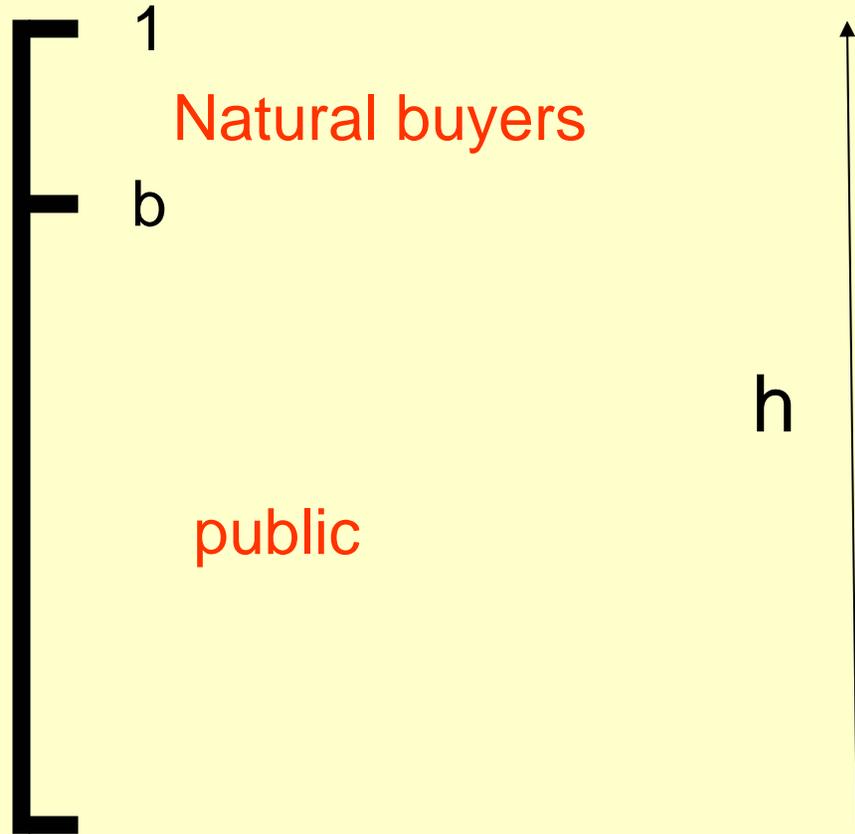

Simple example

- X is cigarettes, utility 1 if consumed at any time (no impatience), perfectly durable
- Y is tobacco plant, produces 1 cigarette in good state $s=U$, $R < 1$ in bad state $s=D$.
- All agents $h \in [0, 1]$ begin with 1 unit of Y and 1 unit of X at time 0, with no new source of income.
- Heterogeneous beliefs: agent h attaches probability h to good state.

Equilibrium

- Clearly p_Y will be between 0 and 1, since optimists think it is worth 1 and pessimists 0.
- Biggest optimists $h=1$ will be dying to get their hands on Y , since they will regard it as a sure arbitrage.
- So will get all $h > b$ as buyers, and all $h < b$ as sellers.

Natural Buyers

What are margins?

- Suppose all loans promise 1 cigarette in both states.
- How much will you be able to borrow using one factory as collateral in equilibrium?
- Would think big optimists would be willing to pay higher interest in order to use less collateral, so maybe many contracts actively sold. But NO! **Just one contract.**

Equilibrium Margin

- Just one contract will be traded, the one where 1 factory collateralizes a promise of .2.
- In this example it happens to be the maximal borrowing that has no chance of default.
- Borrowers are agents $h > b$, and lenders are agents $h < b$.

Why Just One Collateral

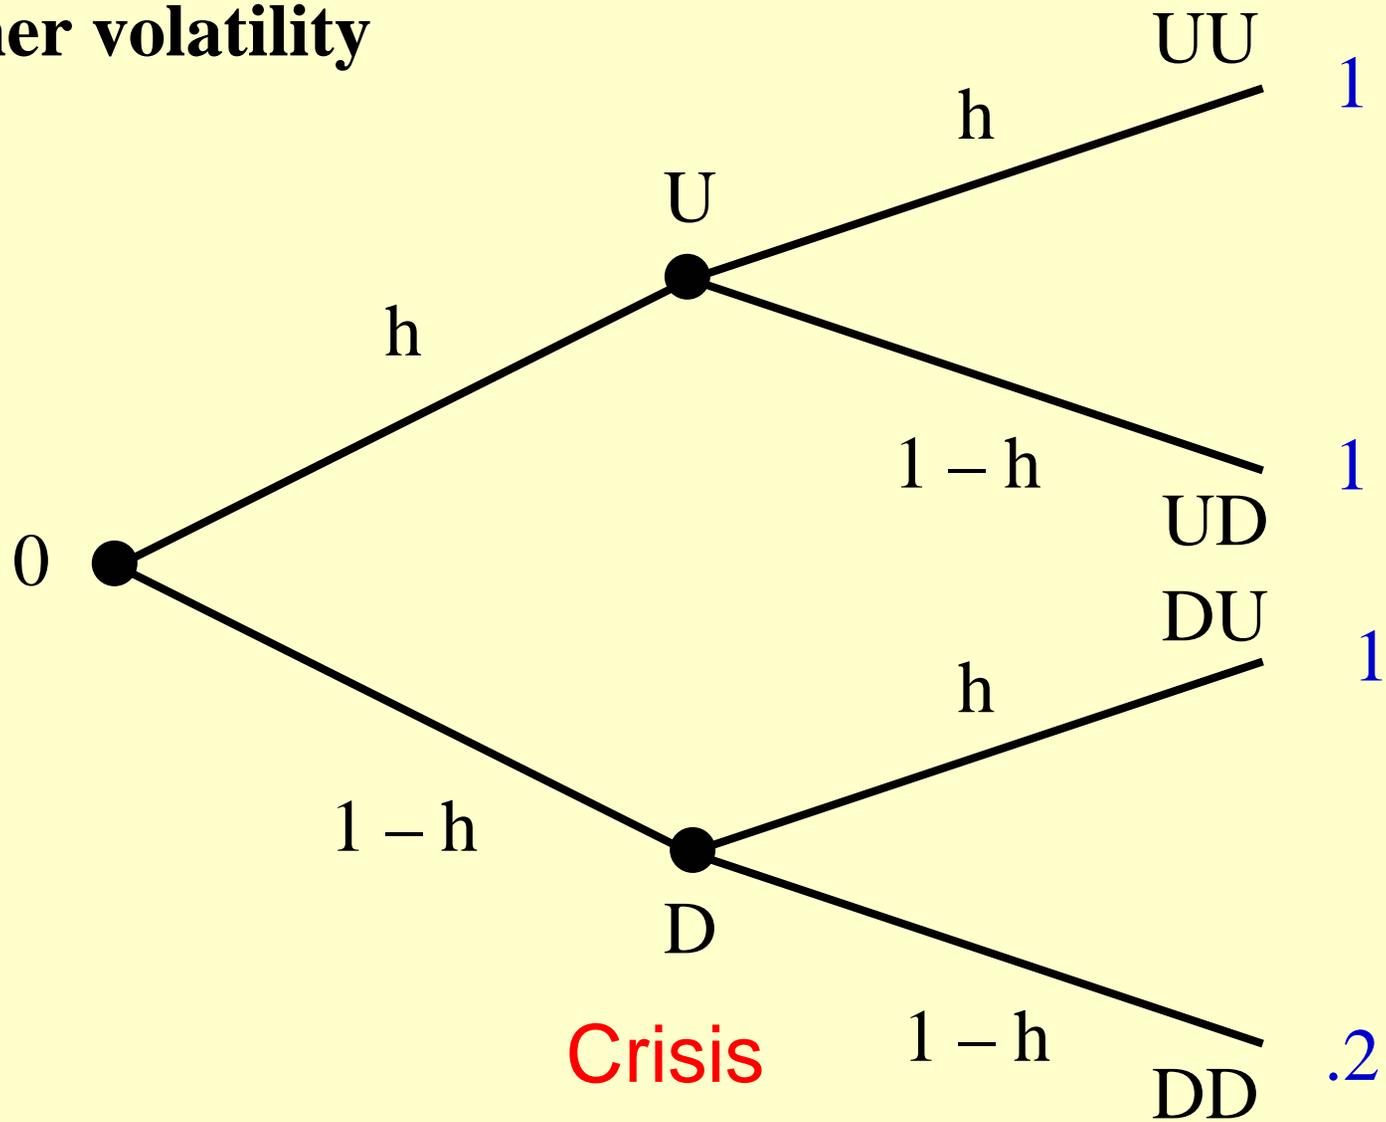

- If no more delivered in D, and more is borrowed, then much more must be delivered in U.
- But that means the borrower is paying more in the state U he is almost sure will happen, and the lender is receiving money in a state he is almost sure will not happen. No deal!

Multi-period example

- Now suppose it takes **two** bad pieces of independent news to get $Y=.2$, and the news comes sequentially.
- Same model as before; every agent begins with 1 unit of X and 1 unit of Y . But now production takes two periods. Loans are still for just one period.

At D lower expectation

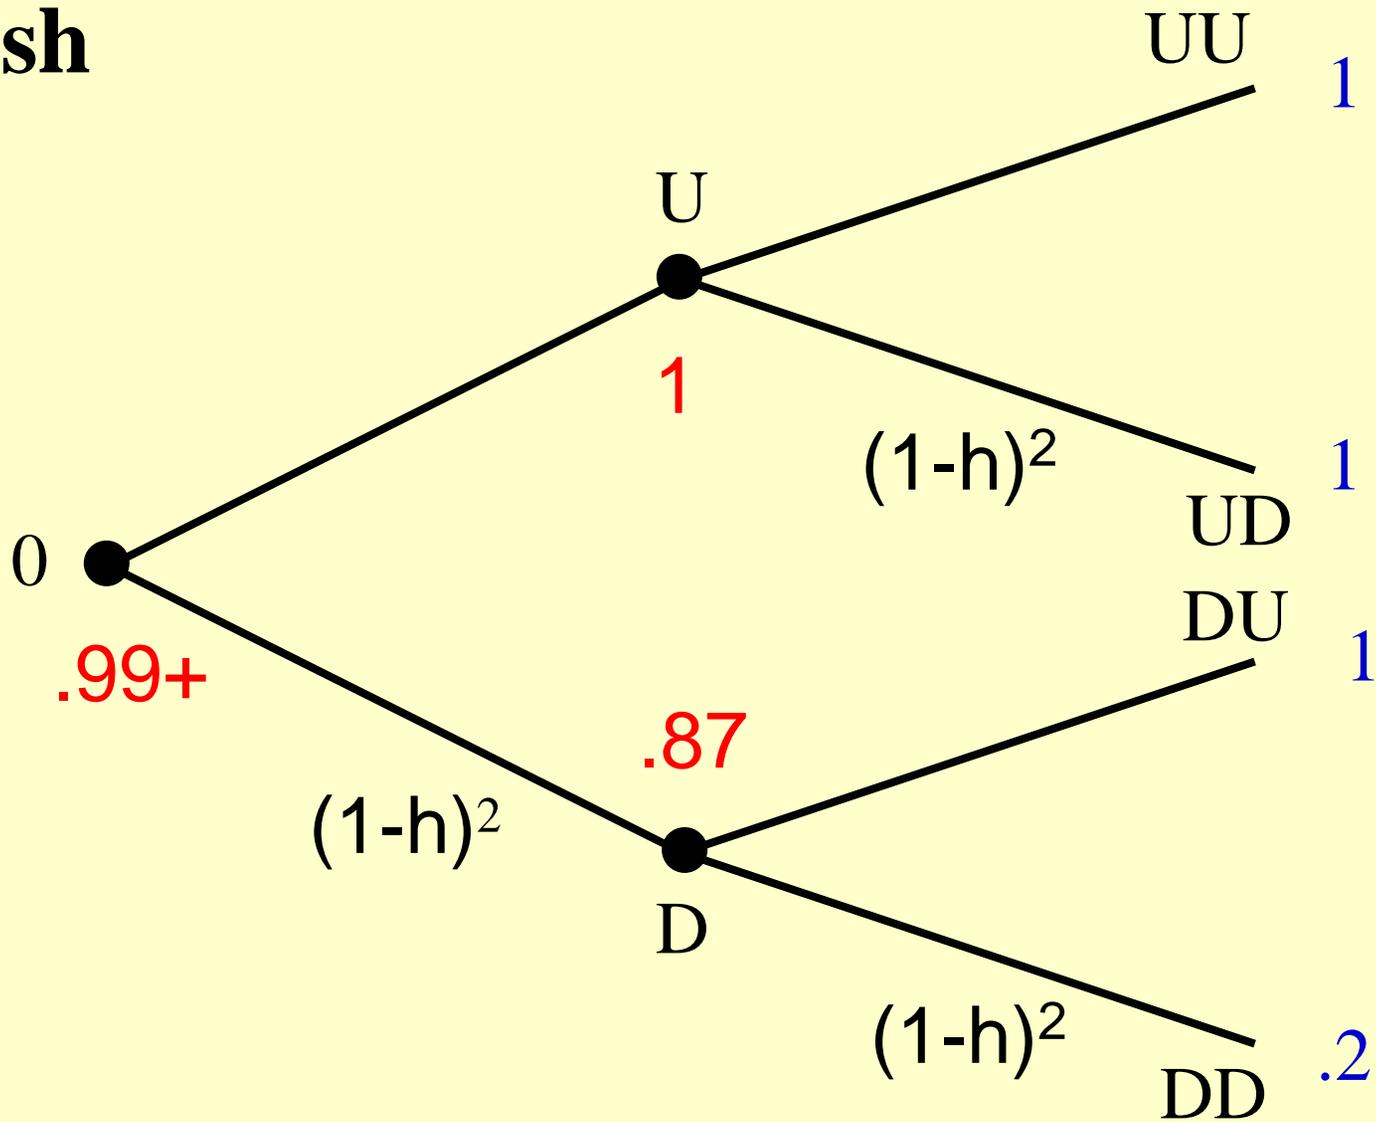

Higher volatility

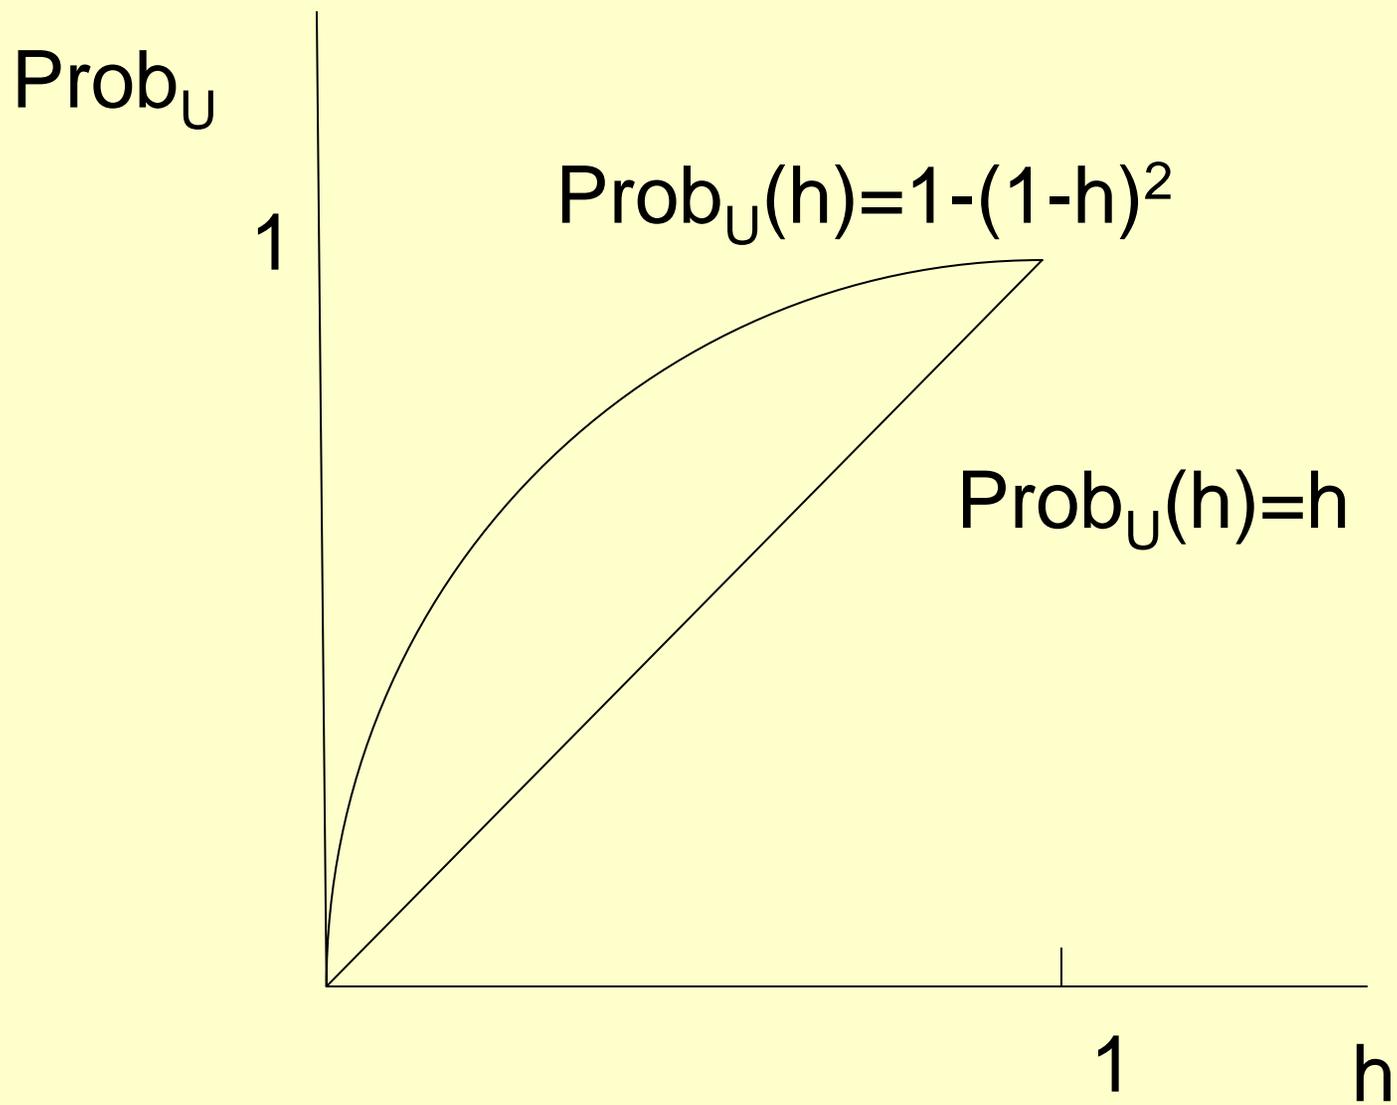

Equilibrium Margins

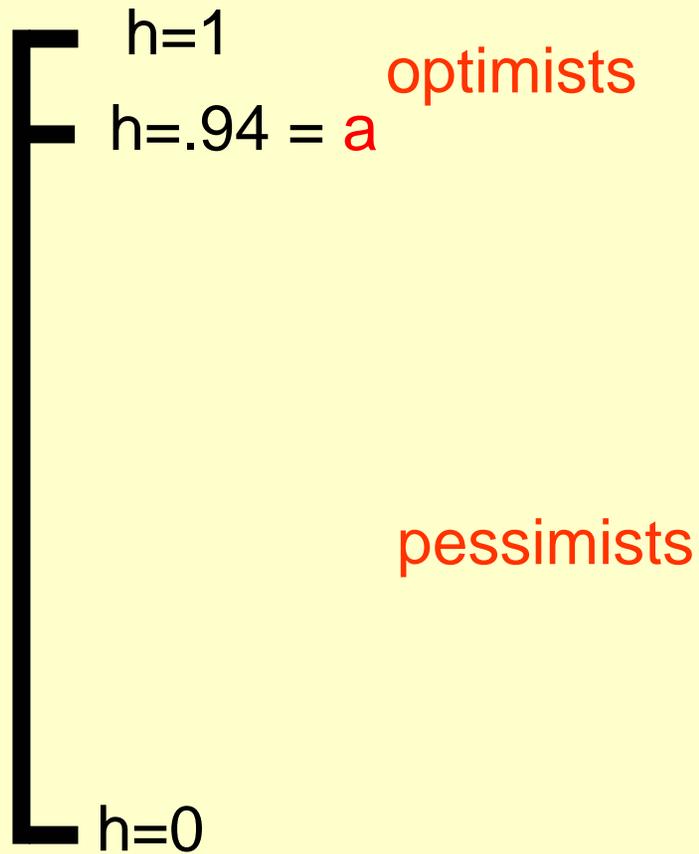

- Equilibrium margin at each node.
- Much tougher at D than at 1 or at U.

Crash

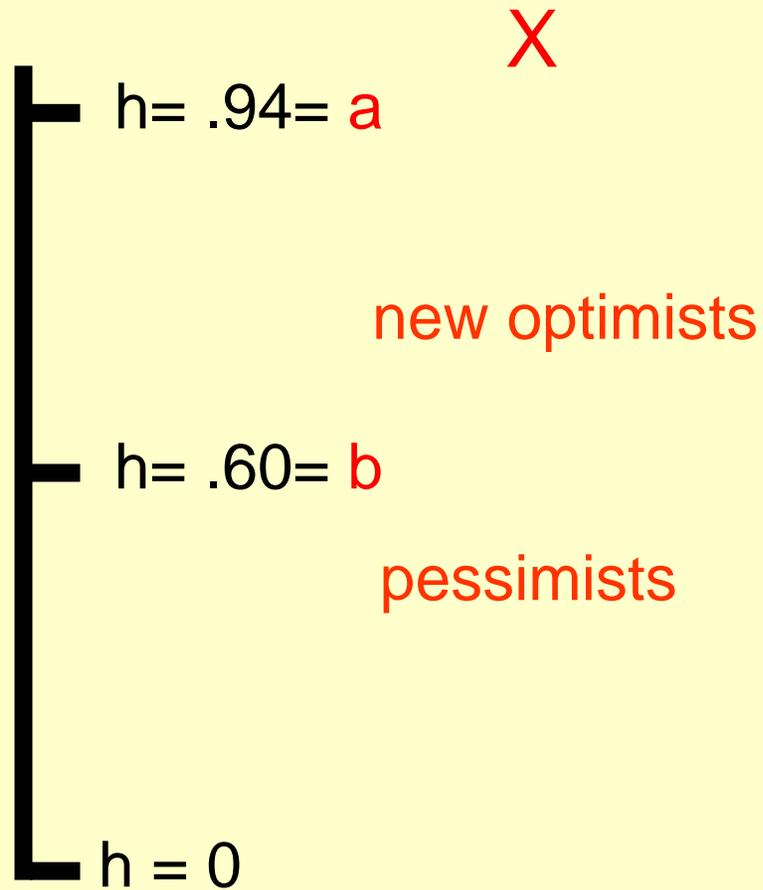

State 0 Marginal Buyer

State D Marginal Buyer

What caused crash?

- Because probability of getting $.2$ goes up, according to a from negligible to $.0036$.
- Because top $6.4\% = 1 - a$ got eliminated.
- Because margin tougher.

- Need all three factors: if only have one, get negligible drop in price, e.g.
 - if bad news from beginning, or
 - if eliminate top 6.4% of people from beginning, or
 - if have tough margins at beginning.

Leverage cycle explains why may
be important to use margins as policy
instruments during crises

Geanakoplos-Kubler 2006 (unpublished)
“Pareto Improving Margins”

shows that market forces do *not* necessarily choose *socially optimal margins*. **Regulating Margins can make everybody better off.**

Regulating margins
also important from a global perspective
to avoid spillovers to different markets,
and not just during a crisis

Fostel-Geanakoplos 2007 (unpublished)

“Emerging Markets in an Anxious Global Economy:
Contagion, Flight to Liquidity, and Issuance Rationing”

shows that with
multiple assets, in an *anxious economy*
endogenous margins also can explain *contagion* and
flight to liquidity.

Anxious Economy

- Crisis is rare event – say every 5 or 10 years.
- But margins get tightened much more frequently on milder bad news.
- Anxious economy happens more often.
- Margin tightening less severe. Price drops smaller.

Anxious Economy Continued

- In the anxious economy the most optimistic buyers are not forced to sell their bad news assets.
- In fact they buy more, because they see bigger opportunity (disagreement has increased).
- Where do they get the money to buy? From selling other assets. Thus get **Contagion**. Assets with no news fall.

Flight to Liquidity

- **Liquidity preference** goes up when liquidity declines, say because volatility increases and margins tightened
- Then the **collateral value** of assets on which one can borrow goes up. Thus **flight to liquidity**.
- Assets on which it is hard to value fall more in price. Thus **flight from illiquidity**.

To sum up:

Endogenous margins requirements can cause, through what we call the *leverage cycle* liquidity shortages, and also crises and crashes in equilibrium.
