Caetano (UGA)

- Segregation in schools, neighborhoods and venues.
- Groups: race, income, gender, age.
- Segregation is a type of inequality.
- Broadly, segregation is the outcome when different groups of people end up in different situations.

• Part of the process that led to segregation involves differential treatment of groups.

- But part of the process that led to segregation is benign.
- The benign part of the process is also consequential.
- The "fair" level of segregation is lower than the current level.

A useful lesson learned in segregation studies

• Sorting \implies Segregation \implies Inequality of main outcome of interest

- Segregation is a type of inequality.
- The "fair" level of segregation is lower than the current level.

A useful lesson learned in segregation studies

- Sorting \implies Segregation \implies Inequality of main outcome of interest
- Segregation is a type of inequality.
- The "fair" level of segregation is lower than the current level.
- But does reducing this inequality \implies reducing inequality of main outcome of interest?
- That is a nontrivial causal question, because the economy is a complex dynamic system.

Salient Inequality v.s. Hidden Inequality

Conclusion

• Inequality in intermediate outcomes is unfair, but reducing it may be more unfair under the current conditions.

Protected groups could be the ones that would pay most of the price for the reduction of inequality.

Conclusion

• Inequality in intermediate outcomes is unfair, but reducing it may be more unfair under the current conditions.

Protected groups could be the ones that would pay most of the price for the reduction of inequality.

- These are complex dynamic systems.
- We need to consider the potential fragility of any algorithm.
 - We need to study the causal effect of an algorithm on business decisions.
 - This will change with the context.
 - Any blind spot which hurts minorities might take longer to be corrected.
 - Other ways to combat unfairness should complement algorithms.

Conclusion

• Inequality in intermediate outcomes is unfair, but reducing it may be more unfair under the current conditions.

Protected groups could be the ones that would pay most of the price for the reduction of inequality.

- These are complex dynamic systems.

Thanks!

Why do different groups tend to end up in different situations? A choice model

Person *i* from group *g* chooses option *j* to maximize utility subject to a constraint:

$$\max_{j \in J_g} U_{igj} = \alpha'_g s_j + \beta'_g x_j + \varepsilon_{igj}$$

s.t. $f_g(s_j, x_j) \le B_{ig}$

 s_j : characteristics of neighbors in j.

 x_j : other attributes of neighborhood j.

- **①** Different choice sets $(J_g \neq J_{g'})$.
- Oroups sort differently on the basis of the composition of neighbors ($\alpha_g \neq \alpha_{g'}$).
- **③** Groups sort differently on the basis of other attributes ($\beta_g \neq \beta_{g'}$).

Different constraints $(f_g \neq f_{g'}, B_{ig} \neq B_{i'g'})$.

Caetano (UGA)
