Federal Deficits: A Faulty Gauge
of Government's Impact on Financial Markets

Health Care: Getting the Right Amount at the Right Price
The BUSINESS REVIEW is published by the Department of Research every other month. It is edited by John J. Mulhern, and artwork is directed by Ronald B. Williams. The REVIEW is available without charge. Please send subscription orders and changes of address to the Department of Research at the above address or telephone (215) 574-6428. Editorial communications also should be sent to the Department of Research or telephone (215) 574-6429. Requests for additional copies should be sent to the Department of Public Services.

The Federal Reserve Bank of Philadelphia is part of the Federal Reserve System—a System which includes twelve regional banks located around the nation as well as the Board of Governors in Washington. The Federal Reserve System was established by Congress in 1913 primarily to manage the nation’s monetary affairs. Supporting functions include clearing checks, providing coin and currency to the banking system, acting as banker for the Federal government, supervising commercial banks, and enforcing consumer credit protection laws. In keeping with the Federal Reserve Act, the System is an agency of the Congress, independent administratively of the Executive Branch, and insulated from partisan political pressures. The Federal Reserve is self-supporting and regularity makes payments to the United States Treasury from its operating surpluses.

by Brian Horrigan and Aris Protopapadakis

In the ongoing debate about the impact of government borrowing on financial markets, the focus usually centers on the size of Federal budget deficits. In the following article, the authors argue that looking only at the deficit can make for misleading conclusions about government’s influence on the credit markets. They propose a more comprehensive measure which often behaves differently than the Federal deficit. The views expressed here are those of the authors and should not be identified as official views of the Federal Reserve Bank of Philadelphia or the Federal Reserve System. — Donald J. Mullineux, Senior Vice President and Chief Economist, Federal Reserve Bank of Philadelphia.

Newspapers and magazines frequently warn about the dangers of big Federal budget deficits, claiming that the recent large deficits have pushed interest rates to record highs. The continuing debate over tax and expenditure cuts illustrates the importance many people attach to Federal budget deficits. Projections of large deficits appear to have prompted the Administration to request more expenditure cuts for 1982, and those projections have sparked a lively debate within the Administration on whether to propose sizable tax increases for 1983. Some members of Congress continue to advocate rolling back recent tax cuts or increasing other taxes in order to reduce the deficit.

People are concerned about budget deficits because they equate them with increased government borrowing from the private sector and increased government competition with private investors. They fear that when the U.S. Treasury borrows more, fewer funds will be available for private investment and interest rates will rise. But does a bigger budget deficit necessarily mean that

*Brian Horrigan received his Ph.D. from the Univer-
sity of California at Los Angeles and joined the Phila-
delphia Fed in 1980. He specializes in monetary and
financial economics. Aris Protopapadakis is Research
Officer and Economist at the Philadelphia Fed. He
received his Ph.D. from the University of Chicago.
the government sector is a bigger drain on credit markets? We argue that the deficit is not a reliable indicator of government’s drain on credit markets. The Federal deficit is an incomplete measure of government borrowing because it does not include all government borrowing. More importantly, all government borrowing must be adjusted for inflation before it can be used as a gauge of government’s competition with private borrowers. An alternative measure which we call “government net borrowing” accounts for all government borrowing and is adjusted for inflation to do a better job of gauging government’s drain on the credit markets.

GOVERNMENT GROSS BORROWING

So far as the credit markets are concerned, what matters is how much the government sector borrows from the public. The Federal budget deficit measures only part of the government sector’s borrowing activity. Other government units and related bodies—such as off-budget Federal agencies and state and local governments—also compete for funds in the credit markets by issuing their own debt, and these agencies often lend funds to the Treasury as well. To obtain the right total, the borrowing of all government units has to be added together and what they lend to each other has to be subtracted out.

We label the resulting magnitude “government gross borrowing.” Government gross borrowing measures the amount of money the government sector borrows from the public.

Off-Budget Agencies Borrow, Too... The Federal government borrows funds that do not appear in the Federal budget. Federally owned agencies, such as the Postal Service and the Tennessee Valley Authority, have the authority to borrow in the credit markets, but their activity does not explicitly appear anywhere in the unified Federal budget. Also, some Federally sponsored agencies, such as the Farmers’ Home Administration and the Rural Electrification Administration, can borrow directly from the Treasury via the Federal Financing Bank. The Treasury lends to these agencies and to the Federal Financing Bank by borrowing directly from the public. This kind of Treasury borrowing also does not appear in the unified Federal budget. Thus, even if the unified budget is balanced, gross borrowing from the public can be large.

The annual increase in total Federal debt includes all Federal borrowing, whether the Treasury is involved in it or not. Column 1 in Figure 1 gives the Federal budget deficit as reported by the Treasury while column 2 in Figure 1 gives total Federal borrowing. The data show that in some years total Federal borrowing was over $20 billion more than the Federal budget deficit.

In addition to off-budget borrowing, there are other government obligations that should be taken into account in a comprehensive measure of the debt (see WHAT IS FEDERAL DEBT? overview). Since it is not possible to measure these obligations accurately, we do not include them in the calculations that follow. Adding accurate estimates of these obligations to the measures of borrowing developed here could change some of the conclusions.

3 For example, as of the end of June 1981, the Student Loan Marketing Association (SLMA) owned $3.4 billion of Federally guaranteed student loans. The SLMA purchased the loans by issuing debt. The Federal Financing Bank (FFB) purchased the SLMA debt by issuing its own debt, and the Treasury in turn purchased the FFB debt. In effect, the Treasury borrowed money from the public to lend to students.

†Preliminary estimates.

**SOURCES:**

Federal deficits are from the Economic Report of the President 1982. Deficits are calculated by the NIPA method, which is based on accrual, unlike the unified budget deficit, which is based on cash flow. Before 1972-73, Federal debt outstanding, Federal debt held by agencies, Federal debt held by state and local governments, and Federal debt held by the Federal Reserve are taken from the Annual Statistical Digest (1970-1979). After 1976, these data are taken from the Federal Reserve Bulletin, January 1982. State and local debt outstanding data are from p. 38, line 2, while internal holdings of state and local debt and holdings of the retirement funds are from p. 39, line 6 and 15 respectively.
WHAT IS FEDERAL DEBT?

In this article, we define the Federal debt as the sum of all the notes, bonds, and bills issued by the Treasury and other Federally owned agencies. But is this all the Federal debt? Debt is nothing more than an obligation, and the Federal government has many obligations that do not take the form of Treasury debt. An important example of obligations not included in the Federal debt is the Federal program of loan guarantees for private debt. The Federal government guarantees hundreds of billions of dollars of private loans against default risk, and it also has assumed hundreds of billions of dollars' worth of insurance commitments. According to the Treasury (as reported by J. S. Nove and World Report, May 4, 1981), Federally guaranteed private loans were $323.6 billion in 1980, and Federal Insurance commitments were $2,217.4 billion.

The majority of the loan guarantees are for mortgages and housing loans ($219.7 billion). It would be absurd to add private mortgages to the national debt just because the Federal government guarantees the mortgages. If, by chance, none of the mortgages defaulted, the guarantees would cost the Treasury nothing. But if all of the mortgages defaulted, the Treasury would be stuck with having to pay off all of the mortgages. It would also end up owning the housing behind these mortgages. A second strategy for the "Treasury is not to include loan guarantees in the Federal debt; instead it could create a sinking fund to cover loan defaults, and make a fixed payment into the sinking fund every year. The annual payment would have to be large enough to keep the fund liquid and should be adjusted with the default experience. That way, the cost of these guarantees would appear in the budget, and Congress and the public would be forced to recognize and deal with the cost of loan guarantees. The same principle applies to insurance commitments.

Another serious problem with measuring the Federal debt concerns the actuarial deficits of the retirement and compensation programs of the Federal government. The Federal government obligates itself to pay retirement benefits to members of the armed forces and the Civil Service. It cannot morally renge on those obligations. If the government does not fund the retirement programs (as private pension and life insurance programs do), then the debt of the Federal government increases—that is, the government has committed itself to pay benefits for which it doesn't have funds. In 1980, the actuarial deficit of retirement and compensation programs (military, Civil Service, veterans, railroad, Foreign Service, Public Health Service) was estimated at $38.3 billion. These liabilities are part of the Federal debt and should be included in it. If the government commits itself to funding these liabilities fully, then it should create an asset position that exactly offsets its total pension liabilities. We have not included unfunded pension liabilities in the estimates of government net borrowing only because the estimates of the actuarial deficits are unreliable.

The above principle does not apply to Social Security. Social Security beneficiaries and taxes are set by Congress and may be changed at any time. The $1,464-billion actuarial deficit of the Social Security trust funds in 1980 only indicates that Social Security needs reform, not that the Federal debt is mismeasured. Changes in the law could easily eliminate the entire actuarial deficit of the Social Security Administration.

As Do State and Local Governments. Even adding in the off-budget Federal agencies doesn't give a complete picture of government financing activity occurs at the state and local levels. It does not matter to private borrowers whether the Federal, state, or local government competes with them for available funds. Therefore, from the viewpoint of the private credit markets, the correct measure of government borrowing must include Federal, state, and local government borrowing, not Federal borrowing alone.

Column 3 in Figure 1 shows the annual borrowing of the combined Federal, state, and local governments for the past decade.
The consolidated government borrowing is always larger than Federal borrowing alone, and it is much larger than the Federal deficits. For instance, though the 1979 Federal deficit was less than $15 billion, total government borrowing was almost $75 billion. But not all of the increases in the Federal, state, and local debt represent a drain on private credit markets; some of this debt is purchased by Federal agencies, by the Federal Reserve System, and by state and local governments.

Not All Government Debt Is Held by the Public. A sizable portion of Federal debt is currently owned by Federal agencies, primarily the Social Security Administration. Since Social Security receipts almost always exceed outlays (they have in 9 of the last 10 years), the Social Security Administration purchases more Federal debt each year. Debt issued by the Treasury doesn't affect the credit markets if it is purchased by a Federal agency such as the Social Security Administration. Thus, increases in debt holdings of Federal agencies must be subtracted from the total increase in Federal debt. Increases in the Federal Reserve System holdings of Treasury debt must be subtracted for the same reason.4

And so must holdings of state and local governments. These governments typically are prohibited by their constitutions from running current account deficits. On average, they run surpluses which they often use to purchase their own debt and Treasury debt. To gauge the impact of government borrowing in the credit markets, increases in state and local government debt holdings must be subtracted from the total increase in government debt as well.

The calculations for 1980 illustrate the magnitude of the adjustments discussed above. In 1980, Federal debt increased by $84.5 billion while the state and local debt increased $24.4 billion, for a total increase of $108.9 billion. Of this increase, the Fed purchased $3.8 billion, Federal agencies purchased $3.4 billion, and state and local governments purchased an additional $9.4 billion. Thus, only the remaining $90.3 billion of government debt was available for purchase by the public.

Column 4 in Figure 1 shows the increases in the consolidated government debt held by the public—government gross borrowing. This borrowing is always larger than the reported Federal budget deficit, but in some cases it is smaller than the increases in total Federal debt. Gross borrowing is smaller than increases in the Federal debt whenever agencies, the Federal Reserve, and state and local governments buy back more debt than they issue.

Gross borrowing is an accurate measure of the money government borrows from the public to finance its expenditures. Compared to this measure, Federal deficits understate the amount of money government borrows. But even gross borrowing may be an inadequate and misleading measure of the government sector's impact on credit markets, because assumption that consumers consider purchases of government debt and private corporate debt equivalent. Consumers do not realize that excess government debt may mean increased future taxes. There is not much disagreement, however, that individuals do not view purchases of bonds (government or private) and money as being equivalent. Thus the response of the financial markets to increases in the supply of reserves (and consequently money) will be different than their response to increases in the supply of government bonds, so that reserves and government debt should not be added together.
gross borrowing greatly depends on the inflation rate. Gross borrowing seriously overstates government's impact on credit markets when prices are rising, because inflation increases the interest rate government must pay on its debt while it reduces the real value of government bonds held by the public.

GOVERNMENT BORROWING AND CREDIT MARKETS: WHAT'S THE CONNECTION?

A higher inflation rate automatically results in larger government gross borrowing, because interest rates are higher when inflation is higher. But does an inflation-induced rise in government borrowing mean that the government is competing for more funds in the credit markets? Only when gross borrowing rises more rapidly than prices is government a drain on the credit markets.

Therefore, gross borrowing figures need to be adjusted for the effect of inflation to get a good measure of government's impact on credit markets.

As inflation increases, the interest that government pays on its debt rises.5 The higher interest compensates bondholders for the inflation-caused erosion of the real value of their bonds (see INFLATION AND INTEREST RATES). If these people are to restore the purchasing power of their bond holdings, they must use the portion of the interest payment that compensates them for inflation—the inflation premium—to purchase additional bonds. Therefore, increases in government debt that keep the real value of the debt constant don't add to government's claims on the financial resources available for private investment.

Inflation causes government borrowing requirements to increase. But this increased demand for funds can be met by the private sector without affecting consumption and investment, because the inflation premium makes enough funds available to finance the additional borrowing. Therefore, judging the impact of government borrowing in the credit markets without accounting for the effect of inflation is highly misleading. In fact, two economies can be identical in real terms, but if they experience different inflation rates, the government deficits and the amounts of new debt the two governments must issue can behave very differently.

Figure 2 gives an example of two such hypothetical economies. Transylvania and

---

5The Federal government alone has accumulated a large debt ($1 trillion), and a significant part of its budget goes to interest payments on this debt (almost $96 billion in fiscal 1982).
Ruthenia have the same unchanging real (inflation-adjusted) consumption and investment, real interest rates, real government purchases and taxes, and real national debt. The two economies have different rates of inflation, though. Transylvania has no inflation, while Ruthenia maintains a steady 10-percent rate of inflation. Every year, Ruthenia’s nominal consumption and investment, nominal government purchases and taxes, and nominal debt rise by 10 percent, but in real terms nothing changes. Transylvania has a balanced budget, while Ruthenia has an ever increasing budget deficit and increasing gross borrowing. Yet this budget deficit (or gross borrowing) has no impact on the Ruthenian economy because the real value of government debt does not change. The budget deficit (100 billion Ruthenian dollars in the first year) is exactly equal to the inflation premium the government pays on its debt, and it serves to keep the real value of the debt constant.

The quantity that correctly measures the

*In billions of Transylvanian and Ruthenian dollars.
impact of government borrowing on the credit markets of both economies is government net borrowing, shown in column 7, Figure 2. Government net borrowing is the change in the real value of the government debt, expressed in current dollars. While gross borrowing is very different for the two countries, net borrowing is the same, reflecting the fact that the two economies are identical except for inflation.

But how is Ruthenia's inflation-induced government gross borrowing financed without causing a drain on the credit markets? The households in Ruthenia provide the funds by saving the inflation premium component of the interest payments on government debt. This is the only saving strategy that allows them to maintain both the real value of their consumption and the real value of their wealth in the face of rising prices. Thus the increase in the dollar savings of the households is just equal to the dollar increase in government borrowing, leaving both real savings and real investment unchanged. A numerical example of a typical Ruthenian household may serve to illustrate the case.

Consider a family with wage income of $25,000 and accumulated savings of $20,000, all invested in one-year government bonds. Suppose there is no inflation and the interest rate is 2 percent, resulting in $400 of interest payments. To simplify the example assume that this family consumes all its wage and interest income—it undertakes no new saving. Over time, its assets (bonds) remain at $22,000 and its consumption at $25,400 (Figure 3, panel a).

If inflation suddenly increases to 10 percent and is expected to stay there, the interest rate rises to 12 percent (fully reflecting inflation), and the family's wages rise at the

(a) Inflation 0%, Interest Rate 2%

(b) Inflation 10%, Interest Rate 12%
10-percent inflation rate (Figure 3, panel b). For the first year, the family’s total income is higher because of the higher interest rates. Can this family still consume all its income and maintain the purchasing power (real value) of its assets? Obviously not, because inflation erodes the purchasing power of its assets. If this family consumed all its new income, by the end of the third year its assets would be worth only $16,529 in today’s Rubenian dollars. Instead, it must save the inflation premium built into the nominal interest rate and buy more government bonds with that money. Only this behavior will allow the family’s real consumption and its real assets to remain the same as before.

Figure 3 (panel b) shows the details of the family’s new saving strategy. The key point is that the inflation premium built into interest rates is not truly income. Rather, it compensates investors for the loss of the purchasing power of their nominal investments (bonds). The family in the example must save all of the inflation premium component of the interest payments to keep its real wealth constant. In dollar terms (though not in real terms), this family is saving more than it used to, making more funds available to buy government bonds.

The examples about government and household finances show that inflation causes budget deficits and government gross borrowing to increase. But this increase can be exactly met by an equal increase in the dollar savings of the households. Thus, though such inflation-induced deficits may seem alarming, large, they are not due necessarily to increases in net borrowing and therefore would not represent a drain on credit markets. Net borrowing is the correct gauge of any potential crowding out of private borrowers from the credit markets.7

The argument so far is made as if inflation is fully anticipated. But, realistically, inflation is never fully anticipated, and forecasts of inflation are often far off the mark. Under these circumstances, is government net borrowing still the correct measure of the government’s impact on the credit markets? As discussed in detail in the Appendix, government net borrowing is a correct measure even when inflation is not fully anticipated.

IS GOVERNMENT A NET BORROWER?

With an inflation-adjusted measure of government borrowing, it is possible to find out whether the government sector might be crowding out private investment by calculating the net borrowing of government.8 Columns 1 and 2, Figure 4 (overtake), show Federal net borrowing and total net borrowing, respectively. These figures show that government net borrowing has been far smaller than the Federal deficit or gross

---

6The examples in the text and in the appendix assume that inflation is neutral—that is, real GNP, the real rate of interest, and real investment are not affected by inflation. Given the current structure of tax laws it is highly unlikely that inflation is neutral in the U.S. However, though inflation may cause some real variables to change at the same time as it increases deficits, we try to focus on the deficits and their impact, leaving out the effects of inflation on the economy. Assuming neutrality greatly

8To compute net borrowing, we use a price index to deflate the end-of-year gross debt. This procedure gives an estimate of real debt. The annual change in real debt gives real net borrowing; multiplying that by the price index gives net borrowing in current dollars. The price index is the geometric average of the GNP deflators for the last quarter of the year and the first quarter of the following year.

*Billions of dollars.
†Based on most recently available estimates.

**SOURCE:** Survey of Current Business. Net real government investment is the annual change in the net physical capital stock owned by the government sector as reported in the National Income and Product Accounts. This capital stock includes all equipment and structures owned by Federal, state, and local government and government-owned enterprises. Net private investment, column 3, is calculated by adding the net private investment shown in the National Income and Product Accounts (Gross investment minus capital consumption allowances) to net consumption of durable goods. Net consumption of durables is calculated by applying a 26-percent depreciation rate to the stock of durables and subtracting that from durables consumption in the National Income and Product Accounts.

borrowing figures would suggest. Often net borrowing is negative; the public reduced its real holdings of government debt in those years. When net borrowing is negative, government in effect supplements savings available for private investment. To the extent that inflation is fully anticipated, negative net borrowing implies a flow of funds to the public. If inflation is completely unanticipated, there is no actual flow of funds. However, the unanticipated capital loss on government bonds will cause households to save more out of their income to rebuild their wealth position. Thus negative government net borrowing in effect increases the supply of private savings.

The figures show that government net borrowing was substantial only during the 1975 recession and the ensuing recovery. There is some government net borrowing also in 1960, the year of a sharp, but short-lived, downturn. It is not surprising that net borrowing, especially Federal net borrowing, rises during recessions; the increase in bor-
borrowing coincides with the recession-induced decline in tax revenues. 10

One way to assess the potential impact of government net borrowing on the credit markets is to compare it to net private investment (see column 3, Figure 4). The data show that net government borrowing was very small relative to net private investment in the last decade. Thus the potential drain of government on the credit markets has been relatively small. For instance, in 1980 net government borrowing was only 12 percent of net investment and in 1978 it was less than 2 percent. Only during the 1975 recession was government borrowing large relative to private investment, and that was a result mainly of the recession.

Another way to gauge the significance of government net borrowing is to compare it to government net investment. Net government investment measures the net addition to the physical capital stock (items such as buildings, bridges, highways, and defense installations) owned by the Federal, state, and local governments. These data are shown in column 4, Figure 4. Government net borrowing is considerably smaller than government net investment, except during periods of recession. Government has been collecting more taxes than it needs in order to finance its current expenditures. All of net borrowing and some tax revenues go to finance government investment projects—a situation which raises policy issues (see SHOULD GOVERNMENT INVESTMENT PROJECTS BE FINANCED WITH TAXES? overleaf).

The results of our analysis show that the size of government net borrowing usually has been small compared to the amount of either private investment or government investment. It is difficult to see how these relatively small amounts of net borrowing could have caused the record high interest rates experienced recently.

Using the concept of government net borrowing can help put the projected budget deficits in perspective. The Administration's most recent forecast is a $97-billion deficit for calendar 1982. This deficit is by far the largest ever. Nonetheless, this large deficit represents only about $46 billion in Federal net borrowing according to our estimates. 11

By historic standards $46 billion of net borrowing is large, but it is much less (47-percent less in real terms) than Federal net borrowing was in 1975—another recession year. Such large net borrowing—and a budget deficit—would only be a problem if it persists after the economy comes out of the recession.

CONCLUSION

Many people are concerned that large Federal deficits cause high interest rates and crowd out private investment. Whatever the validity of the crowding-out hypothesis, the unified Federal budget deficit simply is not the appropriate measure of government's drain on credit markets. The unified Federal budget deficit does not include the borrowing of off-budget Federal agencies and of state and local governments, nor does it exclude the debt purchased by government agencies, by state and local governments, and by the Federal Reserve System. Most importantly, the meaning of the Federal deficit is distorted

10 If the government were to try to hold down its net borrowing by reducing its expenditures and raising taxes during a recession, it would destabilize the economy unnecessarily, and a deeper recession could result. The potential impact of net government borrowing must be evaluated over the business cycle and not year by year.

11 Projections of Federal borrowing for 1982 are from Borrowing and Debt Special Analysis X, released by the Office of Management and Budget. Since detailed 1982 estimates of Federal Reserve, state, and local holdings of Federal debt are not available, we assume that these institutions will behave as they did in 1981. Thus, as a result of a projected increase in Federal debt of $131.3 billion, public holdings have to rise by $95.8 billion. We also adopt the consensus forecast that the GDP deflator will grow by 7.3 percent in 1982.
SHOULD GOVERNMENT INVESTMENT PROJECTS BE FINANCED WITH TAXES?

When a private firm undertakes an investment project, it does not usually suspend dividends and try to finance the project internally. If the firm's credit standing is good and the proposed project is expected to be profitable, it borrows in the market or issues new equity; the new investment generates new cash flows sufficient to pay the additional dividends and interest.

Investment projects, whether private or public, are undertaken because they are expected to yield benefits that exceed the cost of building and maintaining them. The difference between private and public investment projects is that while private projects will be undertaken only when their financial benefits exceed their cost, this rule need not hold for public investment. For example, a local government may decide to build a bridge to alleviate traffic congestion. The local government could finance the bridge from additional tax revenues. But the appropriate financing strategy is to borrow the initial cost of the project and plan to pay for the real portion of its interest charges, for maintenance, and for depreciation with future taxes or tolls. The project will eventually be paid for in either case, but debt finance matches the tax payments the community makes to the benefits it receives more closely than immediate tax finance.

The reason that the government should not finance investment projects with current taxes lies in the role taxes play in the economy. While taxes raise revenues for the government, they also affect the decisions individuals make about labor supply and saving. Evidence suggests that an increase in income and profit taxes decreases saving and labor supply moderately. Financing investment projects from current taxes means that tax rates are higher than they need be, unnecessarily reducing incentives to produce and save.

The Department of Commerce has estimated the net investment of the Federal, state, and local governments. Column 4 in Figure 4 shows that government net investment substantially exceeds government net borrowing except during the 1973 recession and the 1980 downturn. For the last ten years government net borrowing has covered only part of new government investment. The sum of government net borrowing from the public sector from 1973 through 1977 amounts to 68 billion (in 1972 dollars), while the sum of government net investment is 81 billion (in 1972 dollars). Thus a large part of these investments has been and is continuing to be financed by current taxes. This has meant higher taxes and higher tax rates than necessary. The economy could benefit from lower tax rates that would result from financing government investments through borrowing from the public.

The Department of Commerce provides estimates only of the physical/capital stock owned by the government. These estimates do not include financial assets purchased by the government. This exclusion is particularly important for our estimates, because current net borrowing includes off-budget agencies. Some of these agencies, for instance the SLMA, purchase financial assets. However, it is very difficult to estimate the market value of these assets and we do not include them in our net investment figures.

We do not argue here that the taxes collected should always be equal to current expenditures and transfers. Whether optimal revenue raising involves budget deficits or surpluses is not known, because the information necessary to decide that issue is very difficult to find. We only argue that paying for capital projects with current taxes is not an optimal strategy. Furthermore, it is generally agreed that the government should not adjust its taxes and expenditures every year so as to keep its net borrowing constant every year. Rather, the government should allow net borrowing to rise and fall over the business cycle.
by inflation. The inflation of the last decade caused interest rates to rise and therefore caused budget deficits to balloon. These large deficits do not necessarily represent a drain on the credit markets.

Government net borrowing is a better measure of the government sector's impact on credit markets. The net borrowing figures show that government has not been a significant drain on the credit markets. Looking to the future, it is clear that as long as inflation persists, government can run substantial budget deficits without crowding out private investment. But as inflation and inflationary expectations fall, budget deficits will fall without any expenditure cuts or tax increases.

THE CASE OF UNANTICIPATED INFLATION

The examples in the main text on the relationship between inflation, interest rates, and government budget deficits assume that inflation is always fully anticipated. But a 10-percentage-point rise in the inflation rate raises the nominal interest rate from 2 percent to 12 percent only if the public fully anticipates the inflation, and then only if inflation is neutral. If increases in inflation are not fully anticipated, the reported budget deficits will not rise sufficiently to hold the real national debt constant. At the same time, an unanticipated increase in the price level imposes a windfall loss on bondholders.∗

The wealth loss imposed on holders of government bonds by unanticipated inflation is a wealth gain for the government. An inflation-induced drop in the real value of government bonds is equivalent to an increase in the taxes of the bondholders. The real value of the outstanding debt falls, but the interest rate is not high enough to compensate the bondholders for this loss.

The thesis of our article—that the proper measure of the impact of government borrowing is given by the change in the real value of total government debt—does not depend on whether or not inflation is unanticipated. It is easiest to see why by considering again the inflationary economy of our example, Ruthania.

If the Ruthenian inflation is anticipated, the additional financing needs of the government equal the inflation premium of the interest payment—$100 billion. But what if the inflation is not anticipated at all? As long as the government takes no action, there would be no budget deficit and the net borrowing would be $100 billion. This sum is the same as the purchasing power loss suffered by the bondholders. If the government uses net borrowing as a guide for its fiscal policy and tries to keep net borrowing constant, it would attempt to return to its original net borrowing, $0 in this example. It can do so by either increasing transfer payments or cutting taxes and running a $100-billion budget deficit. If it cuts taxes by $100 billion, individually in the economy who suffered capital losses on their bondholdings will use these unanticipated taxes to restore their portfolio without changing their consumption or saving plans (taxes are unanticipated because the inflation was unanticipated). But since the government, by running a $100-billion deficit, is providing the right quantity of bonds the public needs for the rebuilding of portfolios, consumption and investment will remain the same, whether or not the inflation is anticipated.

∗If, for example, bondholders require a 5-percent real return on their investment and they expect a 6-percent inflation rate, the nominal interest rate would be 6 percent. Should the actual inflation rate turn out to be 10 percent, the bondholders realize a real return on their investments of 5 percent. Under these circumstances, government net borrowing may not be the only information necessary to gauge government's impact on the credit markets.
